Introduction

Congratulations on choosing to study A Level Maths. This booklet will help you prepare by brushing up on some of the skills you have learned at GCSE. We will not have time to re-teach these topics in class, but you will need to be **fluent** in them to be able to learn the A Level content, so if you don't currently have a good grasp of these topics you need to work on them **NOW** so that you can start with confidence.

Mathematical fluency does not simply mean that you have met this topic before and think that you remember how to do it. To reach fluency, you must be able to **quickly** and **accurately** recall concepts and methods.

There will be a test on the topics from this booklet in the first week of term. It is expected that A Level students will demonstrate an excellent understanding of these topics.

Please bring your completed and self-marked work from this booklet to your first maths lesson in September to show your teacher.

Differences between GCSE and A Level maths:

GCSE Maths	A Level Maths
If you're naturally good at maths you can do well without much extra studying.	Everybody will need to do a lot of study outside of class.
It's the answer that matters most, but you should show working.	It's the method that matters, not the answer. Often you are given the answer and you need to show steps in the method.
You have an exercise book to keep all your work together.	You will need to keep neat, accurate and well-ordered notes and work in your folder.
How you present your work is not overly important, as long as you get there in the end.	How you present your work can make a big difference to whether you get the right answer at all and whether anyone can understand your method.

Expanding brackets and simplifying expressions

A LEVEL LINKS

Scheme of work: 1a. Algebraic expressions – basic algebraic manipulation, indices and surds

Key points

- When you expand one set of brackets you must multiply everything inside the bracket by what is outside.
- When you expand two linear expressions, each with two terms of the form $ax + b$, where $a \neq 0$ and $b \neq 0$, you create four terms. Two of these can usually be simplified by collecting like terms.

Examples

Example 1 Expand $4(3x - 2)$

$$4(3x - 2) = 12x - 8$$

Multiply everything inside the bracket by the 4 outside the bracket

Example 2 Expand and simplify $3(x + 5) - 4(2x + 3)$

$$\begin{aligned} 3(x + 5) - 4(2x + 3) \\ = 3x + 15 - 8x - 12 \\ = 3 - 5x \end{aligned}$$

- 1 Expand each set of brackets separately by multiplying $(x + 5)$ by 3 and $(2x + 3)$ by -4
- 2 Simplify by collecting like terms:
 $3x - 8x = -5x$ and $15 - 12 = 3$

Example 3 Expand and simplify $(x + 3)(x + 2)$

$$\begin{aligned} (x + 3)(x + 2) \\ = x(x + 2) + 3(x + 2) \\ = x^2 + 2x + 3x + 6 \\ = x^2 + 5x + 6 \end{aligned}$$

- 1 Expand the brackets by multiplying $(x + 2)$ by x and $(x + 2)$ by 3
- 2 Simplify by collecting like terms:
 $2x + 3x = 5x$

Example 4 Expand and simplify $(x - 5)(2x + 3)$

$$\begin{aligned} (x - 5)(2x + 3) \\ = x(2x + 3) - 5(2x + 3) \\ = 2x^2 + 3x - 10x - 15 \\ = 2x^2 - 7x - 15 \end{aligned}$$

- 1 Expand the brackets by multiplying $(2x + 3)$ by x and $(2x + 3)$ by -5
- 2 Simplify by collecting like terms:
 $3x - 10x = -7x$

Factorising expressions

A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

Key points

- Factorising an expression is the opposite of expanding the brackets.
- A quadratic expression is in the form $ax^2 + bx + c$, where $a \neq 0$.
- To factorise a quadratic equation, find two numbers whose sum is b and whose product is ac .
- An expression in the form $x^2 - y^2$ is called the difference of two squares. It factorises to $(x - y)(x + y)$.

Examples

Example 1 Factorise $15x^2y^3 + 9x^4y$

$$15x^2y^3 + 9x^4y = 3x^2y(5y^2 + 3x^2)$$

The highest common factor is $3x^2y$.
So take $3x^2y$ outside the brackets and then divide each term by $3x^2y$ to find the terms in the brackets

Example 2 Factorise $4x^2 - 25y^2$

$$4x^2 - 25y^2 = (2x + 5y)(2x - 5y)$$

This is the difference of two squares as the two terms can be written as $(2x)^2$ and $(5y)^2$

Example 3 Factorise $x^2 + 3x - 10$

$$b = 3, ac = -10$$

$$\text{So } x^2 + 3x - 10 = x^2 + 5x - 2x - 10$$

$$= x(x + 5) - 2(x + 5)$$

$$= (x + 5)(x - 2)$$

- 1 Work out the two factors of $ac = -10$ which add to give $b = 3$ (5 and -2)
- 2 Rewrite the b term ($3x$) using these two factors
- 3 Factorise the first two terms and the last two terms
- 4 $(x + 5)$ is a factor of both terms

Exercise 2

1* Factorise.

a $6x^4y^3 - 10x^3y^4$

c $25x^2y^2 - 10x^3y^2 + 15x^2y^3$

b $21a^3b^5 + 35a^5b^2$

2* Factorise

a $x^2 + 7x + 12$

c $x^2 - 11x + 30$

e $x^2 - 7x - 18$

g $x^2 - 3x - 40$

b $x^2 + 5x - 14$

d $x^2 - 5x - 24$

f $x^2 + x - 20$

h $x^2 + 3x - 28$

3* Factorise

a $36x^2 - 49y^2$

c $18a^2 - 200b^2c^2$

b $4x^2 - 81y^2$

Hint

Take the highest common factor outside the bracket.

Extension

4* Simplify $\sqrt{x^2 + 10x + 25}$

5* Simplify $\frac{(x+2)^2 + 3(x+2)^2}{x^2 - 4}$

ANSWERS 2

1 **a** $2x^3y^3(3x - 5y)$ **b** $7a^3b^2(3b^3 + 5a^2)$
 c $5x^2y^2(5 - 2x + 3y)$

2 **a** $(x + 3)(x + 4)$ **b** $(x + 7)(x - 2)$
 c $(x - 5)(x - 6)$ **d** $(x - 8)(x + 3)$

 g $(x - 8)(x + 5)$ **h** $(x + 7)(x - 4)$

3 **a** $(6x - 7y)(6x + 7y)$ **b** $(2x - 9y)(2x + 9y)$

Completing the square

A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

Key points

- Completing the square for a quadratic rearranges $ax^2 + bx + c$ into the form $p(x + q)^2 + r$
- If $a \neq 1$, then factorise using a as a common factor.

Examples

Example 1 Complete the square for the quadratic expression $x^2 + 6x - 2$

$$\begin{aligned}x^2 + 6x - 2 \\&= (x + 3)^2 - 9 - 2 \\&= (x + 3)^2 - 11\end{aligned}$$

1 Write $x^2 + bx + c$ in the form

$$\left(x + \frac{b}{2}\right)^2 - \left(\frac{b}{2}\right)^2 + c$$

2 Simplify

Example 2 Write $2x^2 - 5x + 1$ in the form $p(x + q)^2 + r$

$$\begin{aligned}2x^2 - 5x + 1 \\&= 2\left(x^2 - \frac{5}{2}x\right) + 1 \\&= 2\left[\left(x - \frac{5}{4}\right)^2 - \left(\frac{5}{4}\right)^2\right] + 1 \\&= 2\left(x - \frac{5}{4}\right)^2 - \frac{25}{8} + 1 \\&= 2\left(x - \frac{5}{4}\right)^2 - \frac{17}{8}\end{aligned}$$

1 Before completing the square write $ax^2 + bx + c$ in the form

$$a\left(x^2 + \frac{b}{a}x\right) + c$$

2 Now complete the square by writing $x^2 - \frac{5}{2}x$ in the form

$$\left(x + \frac{b}{2}\right)^2 - \left(\frac{b}{2}\right)^2$$

3 Expand the square brackets – don't forget to multiply $\left(\frac{5}{4}\right)^2$ by the factor of 2

4 $(5x+3)^2 + 3$

b $(x-5)^2 - 28$

Solving quadratic equations by factorisation

A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

Key points

- A quadratic equation is an equation in the form $ax^2 + bx + c = 0$ where $a \neq 0$.
- To factorise a quadratic equation, find two numbers whose sum is b and whose products is ac .
- When the product of two numbers is 0, then at least one of the numbers must be 0.
- If a quadratic can be solved it will have two solutions (these may be equal).

Examples

Example 1 Solve $5x^2 = 15x$

$5x^2 = 15x$ $5x^2 - 15x = 0$ $5x(x - 3) = 0$ <p>So $5x = 0$ or $(x - 3) = 0$</p> <p>Therefore $x = 0$ or $x = 3$</p>	<ol style="list-style-type: none"> 1 Rearrange the equation so that all of the terms are on one side of the equation and it is equal to zero. Do not divide both sides by x as this would lose the solution $x = 0$. 2 Factorise the quadratic equation. $5x$ is a common factor. 3 When two values multiply to make zero, at least one of the values must be zero. 4 Solve these two equations.
---	---

Example 2 Solve $x^2 + 7x + 12 = 0$

$x^2 + 7x + 12 = 0$ $b = 7, ac = 12$ $x^2 + 4x + 3x + 12 = 0$ $x(x + 4) + 3(x + 4) = 0$ $(x + 4)(x + 3) = 0$ <p>So $(x + 4) = 0$ or $(x + 3) = 0$</p> <p>Therefore $x = -4$ or $x = -3$</p>	<ol style="list-style-type: none"> 1 Factorise the quadratic equation. Work out the two factors of $ac = 12$ which add to give you $b = 7$. (4 and 3) 2 Rewrite the b term ($7x$) using these two factors. 3 Factorise the first two terms and the last two terms. 4 $(x + 4)$ is a factor of both terms. 5 When two values multiply to make zero, at least one of the values must be zero. 6 Solve these two equations.
---	---

Example 3 Solve $9x^2 - 16 = 0$

$$9x^2 - 16 = 0$$
$$(3x + 4)(3x - 4) = 0$$

$$\text{So } (3x + 4) = 0 \text{ or } (3x - 4) = 0$$

$$x = -\frac{4}{3} \text{ or } x = \frac{4}{3}$$

- 1** Factorise the quadratic equation.
This is the difference of two squares as the two terms are $(3x)^2$ and $(4)^2$.
- 2** When two values multiply to make zero, at least one of the values must be zero.
- 3** Solve these two equations.

Solving quadratic equations by using the formula

A LEVEL LINKS

Scheme of work: 1b. Quadratic functions – factorising, solving, graphs and the discriminants

Key points

- Any quadratic equation of the form $ax^2 + bx + c = 0$ can be solved using the formula

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

- If $b^2 - 4ac$ is negative, then the quadratic equation does not have any real solutions.
- It is useful to write down the formula before substituting the values for a , b and c .

Examples

Example 7 Solve $x^2 + 6x + 4 = 0$. Give your solutions in surd form.

$$a = 1, b = 6, c = 4$$

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

$$x = \frac{-6 \pm \sqrt{6^2 - 4(1)(4)}}{2(1)}$$

$$x = \frac{-6 \pm \sqrt{20}}{2}$$

$$x = \frac{-6 \pm 2\sqrt{5}}{2}$$

$$x = -3 \pm \sqrt{5}$$

$$\text{So } x = -3 - \sqrt{5} \text{ or } x = \sqrt{5} - 3$$

- Identify a , b and c and write down the formula.

Remember that $-b \pm \sqrt{b^2 - 4ac}$ is all over $2a$, not just part of it.

- Substitute $a = 1$, $b = 6$, $c = 4$ into the formula.

- Simplify. The denominator is 2, but this is only because $a = 1$. The denominator will not always be 2.

- Simplify $\sqrt{20}$.

$$\sqrt{20} = \sqrt{4 \times 5} = \sqrt{4} \times \sqrt{5} = 2\sqrt{5}$$

- Simplify by dividing numerator and denominator by 2.

- Write down both the solutions.

Example 8 Solve $3x^2 - 7x - 2 = 0$. Give your solutions in surd form.

$a = 3, b = -7, c = -2$ $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$ $x = \frac{-(-7) \pm \sqrt{(-7)^2 - 4(3)(-2)}}{2(3)}$ $x = \frac{7 \pm \sqrt{73}}{6}$ <p>So $x = \frac{7 - \sqrt{73}}{6}$ or $x = \frac{7 + \sqrt{73}}{6}$</p>	<ol style="list-style-type: none"> 1 Identify a, b and c, making sure you get the signs right and write down the formula. Remember that $-b \pm \sqrt{b^2 - 4ac}$ is all over $2a$, not just part of it. 2 Substitute $a = 3$, $b = -7$, $c = -2$ into the formula. 3 Simplify. The denominator is 6 when $a = 3$. A common mistake is to always write a denominator of 2. 4 Write down both the solutions.

Surds and rationalising the denominator

A LEVEL LINKS

Scheme of work: 1a. Algebraic expressions – basic algebraic manipulation, indices and surds

Key points

- A surd is the square root of a number that is not a square number, for example $\sqrt{2}, \sqrt{3}, \sqrt{5}$, etc.
- Surds can be used to give the exact value for an answer.
- $\sqrt{ab} = \sqrt{a} \times \sqrt{b}$
- $\sqrt{\frac{a}{b}} = \frac{\sqrt{a}}{\sqrt{b}}$
- To rationalise the denominator means to remove the surd from the denominator of a fraction.
- To rationalise $\frac{a}{\sqrt{b}}$ you multiply the numerator and denominator by the surd \sqrt{b}
- To rationalise $\frac{a}{b + \sqrt{c}}$ you multiply the numerator and denominator by $b - \sqrt{c}$

Examples

Example 1 Simplify $\sqrt{50}$

$\begin{aligned}\sqrt{50} &= \sqrt{25 \times 2} \\ &= \sqrt{25} \times \sqrt{2} \\ &= 5 \times \sqrt{2} \\ &= 5\sqrt{2}\end{aligned}$	<ol style="list-style-type: none">1 Choose two numbers that are factors of 50. Solving linear simultaneous equations using the elimination method

A LEVEL LINKS

Scheme of work: 1c. Equations – quadratic/linear simultaneous

Key points

- Two equations are simultaneous when they are both true at the same time.
- Solving simultaneous linear equations in two unknowns involves finding the value of each unknown which works for both equations.
- Make sure that the coefficient of one of the unknowns is the same in both equations.
- Eliminate this equal unknown by either subtracting or adding the two equations.

Examples

Example 1 Solve the simultaneous equations $3x + y = 5$ and $x + y = 1$

$\begin{array}{r} 3x + y = 5 \\ - \quad x + y = 1 \\ \hline 2x \quad = 4 \\ \text{So } x = 2 \end{array}$ <p>Using $x + y = 1$</p> $\begin{array}{r} 2 + y = 1 \\ \text{So } y = -1 \end{array}$ <p>Check:</p> <p>equation 1: $3 \times 2 + (-1) = 5$ YES equation 2: $2 + (-1) = 1$ YES</p>	<ol style="list-style-type: none"> 1 Subtract the second equation from the first equation to eliminate the y term. 2 To find the value of y, substitute $x = 2$ into one of the original equations. 3 Substitute the values of x and y into both equations to check your answers.
---	---

Example 2 Solve $x + 2y = 13$ and $5x - 2y = 5$ simultaneously.

$\begin{array}{r} x + 2y = 13 \\ + \quad 5x - 2y = 5 \\ \hline 6x \quad = 18 \\ \text{So } x = 3 \end{array}$ <p>Using $x + 2y = 13$</p> $\begin{array}{r} 3 + 2y = 13 \\ \text{So } y = 5 \end{array}$ <p>Check:</p> <p>equation 1: $3 + 2 \times 5 = 13$ YES equation 2: $5 \times 3 - 2 \times 5 = 5$ YES</p>	<ol style="list-style-type: none"> 1 Add the two equations together to eliminate the y term. 2 To find the value of y, substitute $x = 3$ into one of the original equations. 3 Substitute the values of x and y into both equations to check your answers.
---	---

Example 3 Solve $2x + 3y = 2$ and $5x + 4y = 12$ simultaneously.

$(2x + 3y = 2) \times 4 \rightarrow 8x + 12y = 8$ $(5x + 4y = 12) \times 3 \rightarrow \frac{15x + 12y = 36}{7x = 28}$	1 Multiply the first equation by 4 and the second equation by 3 to make the coefficient of y the same for both equations. Then subtract the first equation from the second equation to eliminate the y term.
So $x = 4$	
Using $2x + 3y = 2$ $2 \times 4 + 3y = 2$ So $y = -2$	2 To find the value of y , substitute $x = 4$ into one of the original equations.
Check: equation 1: $2 \times 4 + 3 \times (-2) = 2$ YES equation 2: $5 \times 4 + 4 \times (-2) = 12$ YES	3 Substitute the values of x and y into both equations to check your answers.

Example 4 Solve $2 - 5x \geq -8$

$$\begin{aligned} 2 - 5x &\geq -8 \\ -5x &\geq -10 \\ x &\leq 2 \end{aligned}$$

 - the side opposite the angle θ is called the opposite
 - the side next to the angle θ is called the adjacent.

Straight line graphs

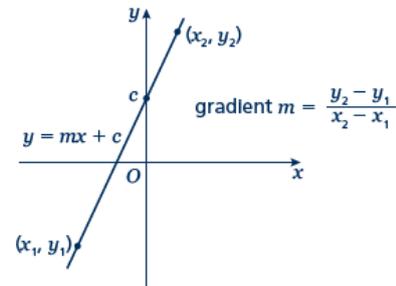

A LEVEL LINKS

Scheme of work: 2a. Straight-line graphs, parallel/perpendicular, length and area problems

Key points

- A straight line has the equation $y = mx + c$, where m is the gradient and c is the y -intercept (where $x = 0$).
- The equation of a straight line can be written in the form $ax + by + c = 0$, where a, b and c are integers.
- When given the coordinates (x_1, y_1) and (x_2, y_2) of two points on a line the gradient is calculated using the

$$\text{formula } m = \frac{y_2 - y_1}{x_2 - x_1}$$

Examples

Example 1 A straight line has gradient $-\frac{1}{2}$ and y -intercept 3.

Write the equation of the line in the form $ax + by + c = 0$.

$$m = -\frac{1}{2} \text{ and } c = 3$$

$$\text{So } y = -\frac{1}{2}x + 3$$

$$\frac{1}{2}x + y - 3 = 0$$

$$x + 2y - 6 = 0$$

- 1 A straight line has equation $y = mx + c$. Substitute the gradient and y -intercept given in the question into this equation.
- 2 Rearrange the equation so all the terms are on one side and 0 is on the other side.
- 3 Multiply both sides by 2 to eliminate the denominator.

Example 2 Find the gradient and the y -intercept of the line with the equation $3y - 2x + 4 = 0$.

$$3y - 2x + 4 = 0$$

$$3y = 2x - 4$$

$$y = \frac{2}{3}x - \frac{4}{3}$$

$$\text{Gradient} = m = \frac{2}{3}$$

$$\text{y-intercept} = c = -\frac{4}{3}$$

- 1 Make y the subject of the equation.
- 2 Divide all the terms by three to get the equation in the form $y = \dots$
- 3 In the form $y = mx + c$, the gradient is m and the y -intercept is c .

Example 3 Find the equation of the line which passes through the point (5, 13) and has gradient 3.

$m = 3$ $y = 3x + c$ $13 = 3 \times 5 + c$ $13 = 15 + c$ $c = -2$ $y = 3x - 2$	<ol style="list-style-type: none">1 Substitute the gradient given in the question into the equation of a straight line $y = mx + c$.2 Substitute the coordinates $x = 5$ and $y = 13$ into the equation.3 Simplify and solve the equation.4 Substitute $c = -2$ into the equation $y = 3x + c$

Example 4 Find the equation of the line passing through the points with coordinates (2, 4) and (8, 7).

$x_1 = 2, x_2 = 8, y_1 = 4 \text{ and } y_2 = 7$ $m = \frac{y_2 - y_1}{x_2 - x_1} = \frac{7 - 4}{8 - 2} = \frac{3}{6} = \frac{1}{2}$ $y = \frac{1}{2}x + c$ $4 = \frac{1}{2} \times 2 + c$ $c = 3$ $y = \frac{1}{2}x + 3$	<ol style="list-style-type: none">1 Substitute the coordinates into the equation $m = \frac{y_2 - y_1}{x_2 - x_1}$ to work out the gradient of the line.2 Substitute the gradient into the equation of a straight line $y = mx + c$.3 Substitute the coordinates of either point into the equation.4 Simplify and solve the equation.5 Substitute $c = 3$ into the equation $y = \frac{1}{2}x + c$

Exercise 10

1 Find the gradient and the y-intercept of the following equations.

- a** $y = 3x + 5$ **b** $y = -\frac{1}{2}x - 7$
c $2y = 4x - 3$ **d** $x + y = 5$
e $2x - 3y - 7 = 0$ **f** $5x + y - 4 = 0$

Hint
Rearrange the equations
to the form $y = mx + c$

2 Copy and complete the table, giving the equation of the line in the form $y = mx + c$.

Gradient	y-intercept	Equation of the line
5	0	
-3	2	
4	-7	

3 Find, in the form $ax + by + c = 0$ where a , b and c are integers, an equation for each of the lines with the following gradients and y-intercepts.

- a** gradient $-\frac{1}{2}$, y-intercept -7 **b** gradient 2, y-intercept 0
c gradient $\frac{2}{3}$, y-intercept 4 **d** gradient -1.2 , y-intercept -2

4 Write an equation for the line which passes through the point (2, 5) and has gradient 4.

5 Write an equation for the line which passes through the point (6, 3) and has gradient $-\frac{2}{3}$.

6 Write an equation for the line passing through each of the following pairs of points.

- a** (4, 5), (10, 17) **b** (0, 6), (-4, 8)
c (-1, -7), (5, 23) **d** (3, 10), (4, 7)

Extension

7 The equation of a line is $2y + 3x - 6 = 0$.
Write as much information as possible about this line.

ANSWERS 10

- 1 **a** $m = 3, c = 5$ **b** $m = -\frac{1}{2}, c = -7$
c $m = 2, c = -\frac{3}{2}$ **d** $m = -1, c = 5$
e $m = \frac{2}{3}, c = -\frac{7}{3}$ or $-2\frac{1}{3}$ **f** $m = -5, c = 4$

2

Gradient	y-intercept	Equation of the line
5	0	$y = 5x$
-3	2	$y = -3x + 2$
4	-7	$y = 4x - 7$

- 3 **a** $x + 2y + 14 = 0$ **b** $2x - y = 0$
c $2x - 3y + 12 = 0$ **d** $6x + 5y + 10 = 0$

4 $y = 4x - 3$

5 $y = -\frac{2}{3}x + 7$

- 6 **a** $y = 2x - 3$ **b** $y = -\frac{1}{2}x + 6$
c $y = 5x - 2$ **d** $y = -3x + 19$

7 $y = -\frac{3}{2}x + 3$, the gradient is $-\frac{3}{2}$ and the y-intercept is 3.

The line intercepts the axes at (0, 3) and (2, 0).

Students may sketch the line or give coordinates that lie on the line such as $\left(1, \frac{3}{2}\right)$ or $(4, -3)$.
